

## Flask contact form email backend not running ▾

```
from flask import Flask, request, jsonify
from flask_cors import CORS
import smtplib
from email.mime.text import MIMEText
from email.mime.multipart import MIMEMultipart
import os
```

[Show more](#)

Looking at your code, a few things could cause it not to run. What error are you seeing?

Q: What error message are you getting?

A: No error but nothing happens

"No error but nothing happens" usually means the script runs and exits immediately — most likely because the `if __name__ == "__main__":` block isn't being reached, or the virtual environment is wrong.

**Try these steps in order:**

### 1. Run it explicitly with Python

```
bash

python app.py
```

You should see:

```
* Running on http://127.0.0.1:5000
```

### 2. If that still does nothing, check your `.env` file exists

Your folder should look like:

```
project/
├─ app.py
├─ .env      ← this must exist
├─ requirements.txt
```

And `.env` should have:

```
env

GMAIL_USER=you@gmail.com
GMAIL_PASSWORD=your_app_password
RECEIVER_EMAIL=receiver@gmail.com
```

### 3. Install all dependencies

```
bash

pip install flask flask-cors python-dotenv
```

### 4. Then run again

```
bash

python app.py
```

---

One real bug in your code — your `.env` values have a comment on the same line, which `dotenv` will include in the value:

```
python

GMAIL_USER      = os.getenv("GMAIL_USER")    # ← this comment is fine in Python
```

But in your `.env` file, make sure there are **no inline comments**:

```
env

# ✅ Correct
GMAIL_USER=you@gmail.com
```

```
# ❌ Wrong – dotenv includes the comment as part of the value
GMAIL_USER=you@gmail.com # your gmail
```

Share the exact terminal output after running `python app.py` and I can help further.

```
{
  "status": "Bulbul Portfolio Backend \u2014 Running \u2713"
} ye aa rha
```

Your backend is running perfectly! 🎉

That response means your Flask server is live and working. The `\u2014` and `\u2713` are just Unicode for `–` and `✓`.

Now test your `/contact` endpoint to make sure email works:

Run this in a new terminal:

```
bash

curl -X POST http://127.0.0.1:5000/contact \
  -H "Content-Type: application/json" \
  -d '{"name": "Test", "email": "test@gmail.com", "phone": "9999999999", "message":
```

**Expected response:**

```
json

{"success": true, "message": "Message bhej diya gaya!"}
```

**If you get an email error instead**, the most common reason is Gmail — you need an **App Password**, not your regular Gmail password:

1. Go to [myaccount.google.com](https://myaccount.google.com)
2. Security → **2-Step Verification** (enable it first)
3. Then search "**App Passwords**"
4. Generate one for "Mail" → copy the 16-character password
5. Put that in your `.env` as `MAIL_PASSWORD`

Share what the curl response says and I'll help from there!

env file me use kiya he gmail and app password

Great, so Gmail config sahi hai. Ab curl test karo aur response share karo:

bash

```
curl -X POST http://127.0.0.1:5000/contact \
  -H "Content-Type: application/json" \
  -d '{"name": "Test", "email": "test@gmail.com", "phone": "9999999999"'
```

Agar Windows (Command Prompt) use kar rahe ho toh quotes ka issue hota hai, isliye Windows wala version diya.

**Response 3 me se 1 aayega:**

**Response**

**Matlab**

`{"success": true}`

✅ Sab kuch kaam kar raha hai

`{"error": "Email send nahi hui"}`

❌ Gmail auth issue

`Connection refused`

❌ Server band ho gaya

Kya aa raha hai?
